

Demonstration of the Server's ability to be run and connected by clients on different networks

Due to the lack of a second laptop and my friend is not always available for testing my chat app, I have instead used my phone and run the python file on the app Pydroid. In the phone, I have turned off my wifi and open 3G mobile data connection, which uses a different network from my wifi router

First of all, I need to check my global IPv4 address. I opened my ASUS account that links to my router. The global IPv4 address of my router is: 87.92.16.209

I set my global IPv4 above as the IP connection address of client_IPv4.py file with port 34000

```
localIPv4 = "192.168.1.208"
globalIPv4 = "87.92.16.209"

# Remember to Disable firewall

port_IPv4 = 34000
buffer = 4096
backlog = 5
```

For my server.py file, the IP address of the server is my local IP address with the port number 34000 for IPv4

```
buffer = 4096
backlog = 5
localIPv4 = "192.168.1.208"
localIPv6 = "fe80::c10c:de5e:2cbf:132c%9"
port_IPv4 = 34000
port_IPv6 = 36000
address_IPv4 = (localIPv4, port_IPv4)
address_IPv6 = (localIPv6, port_IPv6)
```

Now I will carry out port forwarding. I access my ASUS router and set my port forwarding as follows:

Port Forwarding List (Max Limit : 32)						
Service Name	Source Target	Port Range	Local IP	Local Port	Protocol	Add / Delete
<input type="text"/>	<input type="text"/>	<input type="text"/>	<input type="text"/>	<input type="text"/>	TCP	
Anyone		34000	192.168.1.208	34000	TCP	

Local port and Local IP are the IPv4 and port 34000 of my local chat server

Source target is left empty as all clients can send packets to my server. Port range for client would still be 34000 as specified above.

=> Each time any packets on the net is sent to the global IPv4 of my router 87.92.16.209 on the port 34000 will be forwarded to the port 34000 of my chat server.

In order for the different network connection to happen, Firewall has been disabled on my laptop

Requirement 1: The clients can connect to different networks

First user is Binh, connected via the laptop using the wifi of the router (first address - IPv6)

Second user is Hoa, connected via the phone using 3G mobile network (second address - IPv4)

Third user is Dat, connected via the laptop using the wifi of the router (third address - IPv4)

```
PS C:\Users\nguye\Desktop\Basic Principles in Networking\Assignment 2\Instant Message App V2> python -u "c:\Users\nguye\Desktop\Basic Principles in Networking\Assignment 2\Instant Message App V2\server.py"
Waiting for the clients to connect...
fe80::c10c:de5e:2cbf:132c:60836:0:9 has connected.
87.94.111.3:5141 has connected.
192.168.1.1:60857 has connected.
```
